Confirmation

Confirmation is provided to check user choices and actions to prevent the user from making errors. Good confirmation UX prevents user errors by providing them with context and information explaining the direct consequences of taking action without interrupting the user experience. It is possible to establish rules for providing confirmation as shown below, dependent on the type of user action.

Types of action	Destructive action	Constructive action
Cases of action	Delete an item	Create a new item
	Delete data	share with friends
	Stop a process	Upload data
	...	...
General needs of confirmation	Confirmation needed	Confirmation not needed

How to provide confirmation?

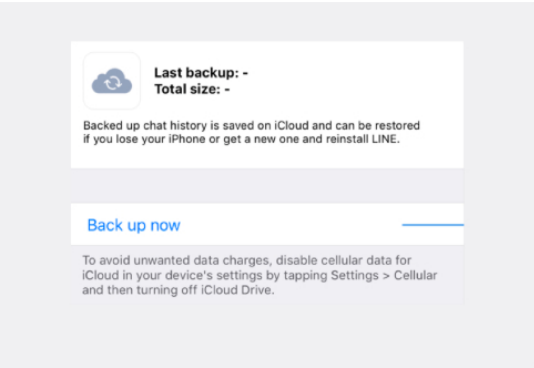

It is not a good idea to simply follow these delivery rules without first considering the context. Excessive use of confirmation can interfere with user experience. Therefore, it is important to provide it appropriately depending on the situation.

These guidelines explain how to provide confirmation with specific examples by context.

Constructive action

Constructive action is a productive and useful action to create new items or share for example. In general, confirmation is not required, but it is recommended in the following cases.

Long wait time

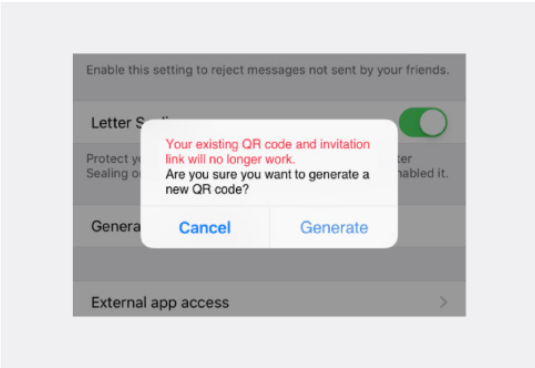

Do

If the task completion wait time is long, for example; uploading large data, provide operation progress and confirmation about the network environment.

Request special manipulation

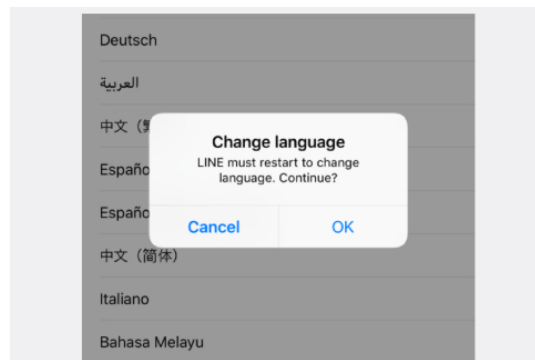

Unrecoverable action

Do

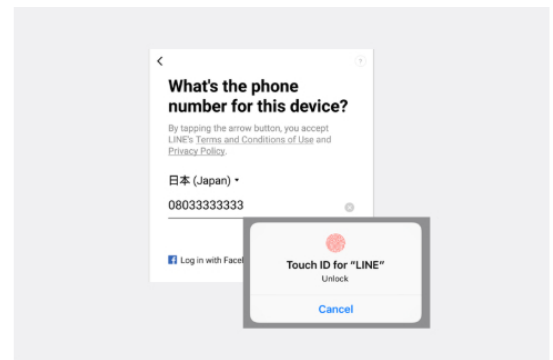

Provide confirmation if the resulting state can not be reversed.

Request personal data / Authentication

Do

Provide confirmation when a user action results in a large change to the overall service.

Do

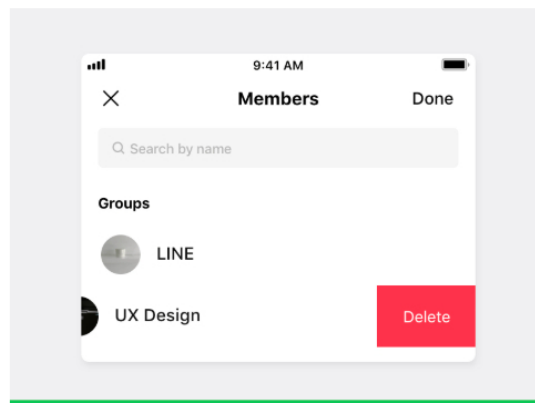

Provide confirmation of user identity through OS native authentication in special situations such as requesting personal information, changing personal information or payment etc.

Destructive action

A destructive action is an action that can not be undone.

Destructive actions typically provide confirmation but it is recommended as an exception in following cases:

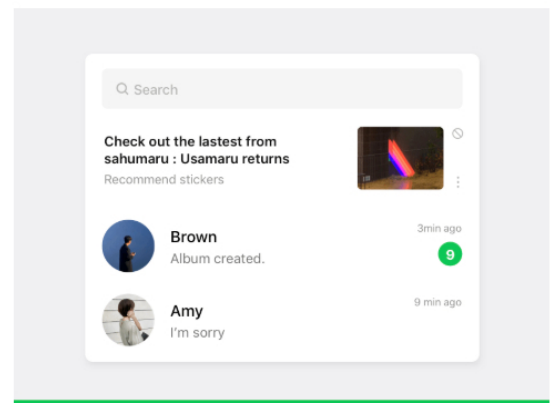

Inline action

Do

Don't provide confirmation when selecting an action by swiping a list in iOS.

Trivial action

Do

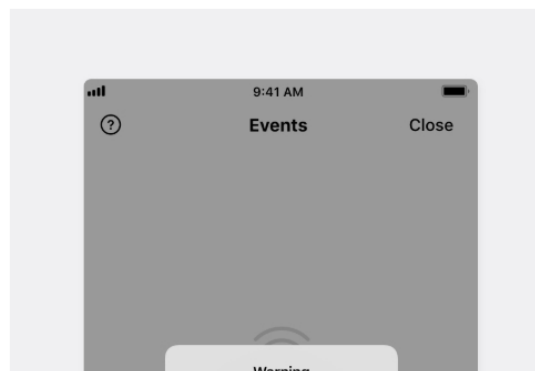

Don't provide confirmation if there is no need to check the user's intentions, such as deleting cache data, removing ads or notifications for example.

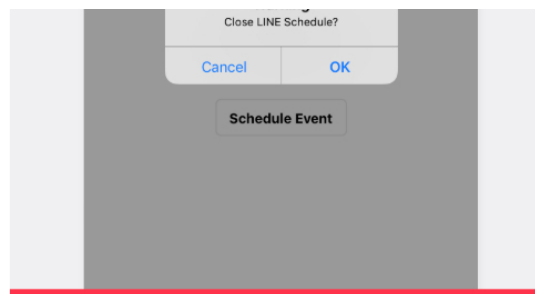

Transition

Transition refers to movement between screens.

Confirmation is not required when the user moves from the current screen to another screen.

Natigation, menu, close, back

Don't

Don't provide unnecessary confirmation when navigating between menus, closing the current screen or selecting the back button.
