LINE Color Guide

LINE Color Palette offers a standard color chart and user guide to help designers create a consistent brand experience. Designers should apply colors purposefully so that users will clearly understand the message from the service.

Primary Color Palette

LINE Apps use the color palette defined below for their main UI components. Note that LINE Green, which represents LINE's brand, was defined for respective OS in consideration of differences in the display environment.

By default, use text above number 500 with a contrast ratio of 3.0: 1 or more to gain Accessibility. Number 400 which is below that, should be used restrictively to the text with least importance if there is a lot of text combinations.

For iOS

Permissible Opacity

In principle, LINE Color Palette does not allow adjusting the opacity of colors on the Palette, except for LINE White and LINE Black. For these two colors, the opacity can be adjusted by 5%.

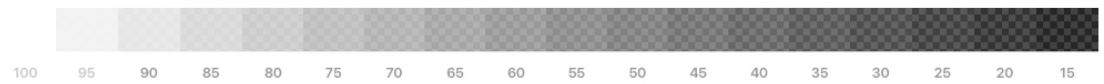

LINE Black

Opacity above 10% can be applied to UI components such as dimmed effect to aid readability. Opacity must not be used for texts, except when there is a special need for visual explanation for unique status including disabled or placeholder.

LINE White

Opacity above 70% should be applied to texts or key icons to ensure readability. It is recommended to apply at least 40% opacity to placeholders while opacity of 15% or higher can be applied to other secondary UI components such button bg.

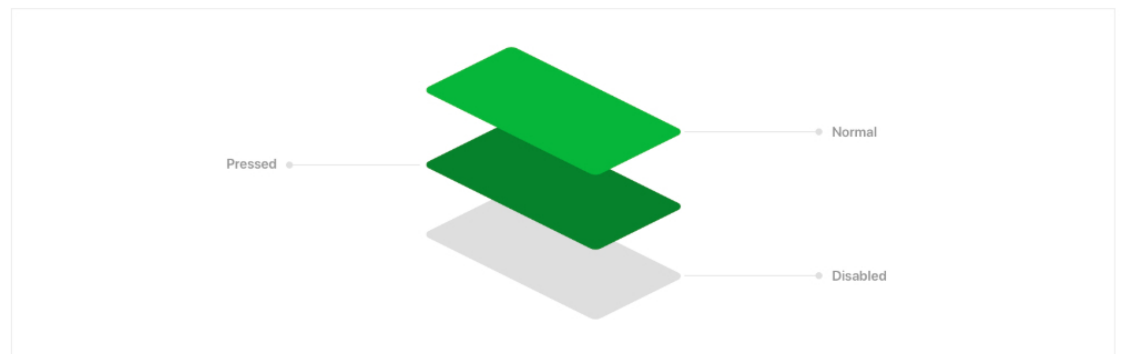

Dimmed Effect

You can choose one of the three dimmed effects below to be applied to overall background images.

States

The colors for the states are specified in the code with certain rules, even if the designer does not specify them. Designers can specify their own depending on the situation.

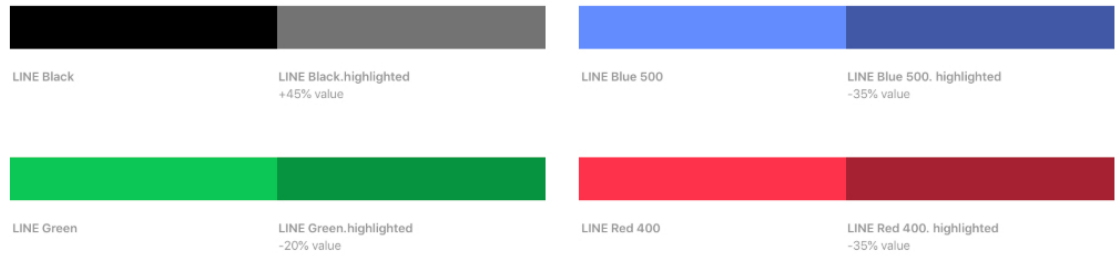

Auto Code for Highlighted color

Highlighted/Pressed colors are created by adjusting the numbers of HSV status converted from RGB value as below.

- When the Value is equal or less than 32%: original Value + 45%
- When the Value is equal or more than 33%, and equal or less than 86% : original Value - 20%
- When the Value is equal or more than 87% : original Value - 35%

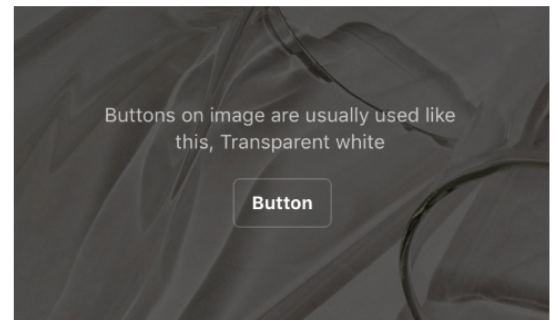

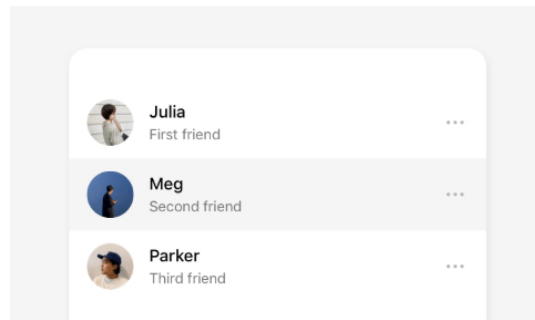

Almost all Semantic Colors and Palette Colors can be converted into highlighted/pressed ones by applying automatic method in the dev phase, unless the colors contain Line White.

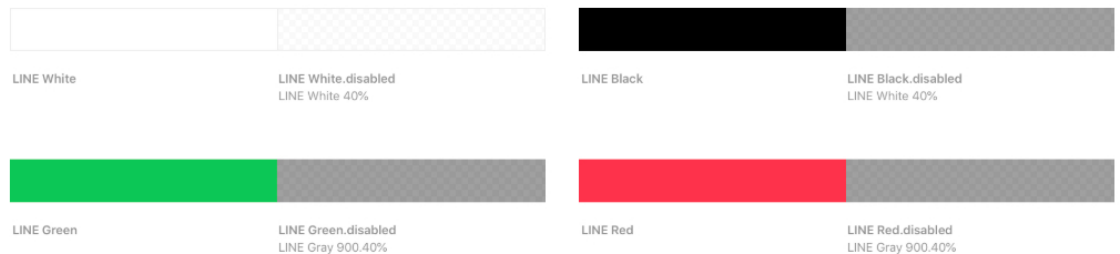

Semantic Keys for Highlighted color

Exceptional cases that cannot be covered by the state color generated by auto code can be handled using the Semantic Color Key. The highlighted color that is lighter than the previous one used in the list and the highlighted color of the transparent button used on the image correspond to the corresponding exception cases using the Semantic key.

Disabled Code

When applying disabled rules, 40% of transparency is applied to LINE white, and 40% of LINE gray 900 is applied to all colors except LINE white. The disabled color, which is automatically assigned to the development code, applies only to the button text (label). Only if a designer wants to emphasize the state by changing the button's bg color itself to a gray scale, he or she specify it and pass it to development. Here are examples of a disabled color that follows that rule.
